ABSTRACT

It is essential to remove herbicide from solution. In this research, composite of Fe-crosslinked chitosan complex (Ch-Fe) was synthesized and characterized by scanning electron microscopy, X-ray fluorescence analysis and was used as adsorbent for removal of 2,4-dichlorophenoxyacetic acid (2,4-D) from solution. Batch experiments were performed to evaluate the effects of several experimental parameters, such as solid-liquid ratio, pH value, coexisting ions, contact time and concentration of 2,4-D. There was slight change of adsorption quantity at various solution pH from 4.0 to 11.0. The kinetic process was better described by the pseudo-second-order kinetic model. The adsorption equilibrium data were better fitted by Langmuir model and Kobler–Corrigan model with higher determined coefficients ($R^2$) and low value of error and this suggested that adsorption be monolayer adsorption and the active sites be all energetically equivalent. The adsorption quantity was 473 mg g$^{-1}$ from experiments at 293 K. Solution of 0.1 mol L$^{-1}$ hydrochloric acid was the best to regenerate spent Ch-Fe and only 9% of adsorption capacity lost after three cycles. The mechanism between 2,4-D and Ch-Fe was discussed. High adsorption capacity and good cycling performance showed the potential application in removal of herbicide from aqueous solutions.
