ABSTRACT

Effect of the ratio of food to microorganism (F/M) ranging from 0.25 to 2.0 and nature of sludge on methanogenesis of phenol in the batch reactors has been evaluated. Unacclimatized flocculant sludge and acclimatized granular sludge were used as seed inocula (microorganisms) in two different sets of experiments. The degradation profiles of phenolic COD conformed to logistic growth model. Lag phases of 10 days with flocculant sludge and up to 32 days with granular sludge followed by accelerated rate of CH\textsubscript{4} generation were noticed. Methane generation rate constant (\(k\)) has been found to vary from 0.17 to 0.21 d\(^{-1}\) and 0.10 to 0.18 d\(^{-1}\) with flocculant and granular sludges respectively. The F/M ratio also influenced the biochemical methane potential (\(\mu\)) and the sludge activity [mL CH\textsubscript{4} or g CH\textsubscript{4}-COD formed/g VSS (sludge)]. \(\mu\) \(_{80}\) at 80 days \((\mu_{80})\) with flocculant sludge ranged from 0.18 to 0.95 while \(\mu\) \(_{112}\) at 112 days \((\mu_{112})\) with granular sludge ranged from 0.80 to 1.04. \(\mu_{80}\) was maximum at F/M = 0.75. The trend of sludge activity was also found similar to that of \(k\) and \(\mu_{112}\).
